

# MIPS assembly language

Pioneered RISC (reduced instruction set architecture) in the 1980s

The most widely taught assembly language

Easy to transition from MIPS to ARMv8

Recently acquired by Wave Computing, will be aligned with RISC-V

# Hello World in MIPS

Two sections:

.data - for static data

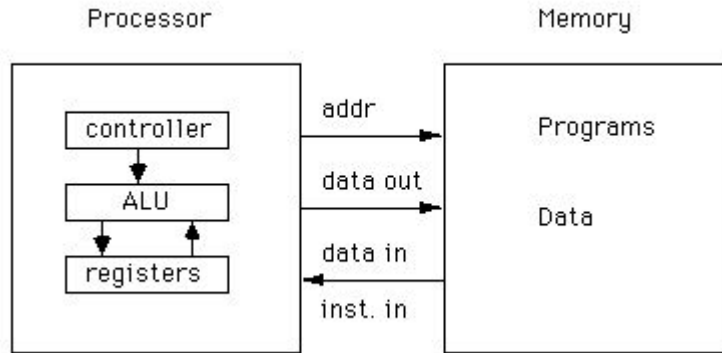

.text - for code

- Program ends with a syscall to end the program
- Think of this like return(0) in C
- Syscalls need the call number in \$v0

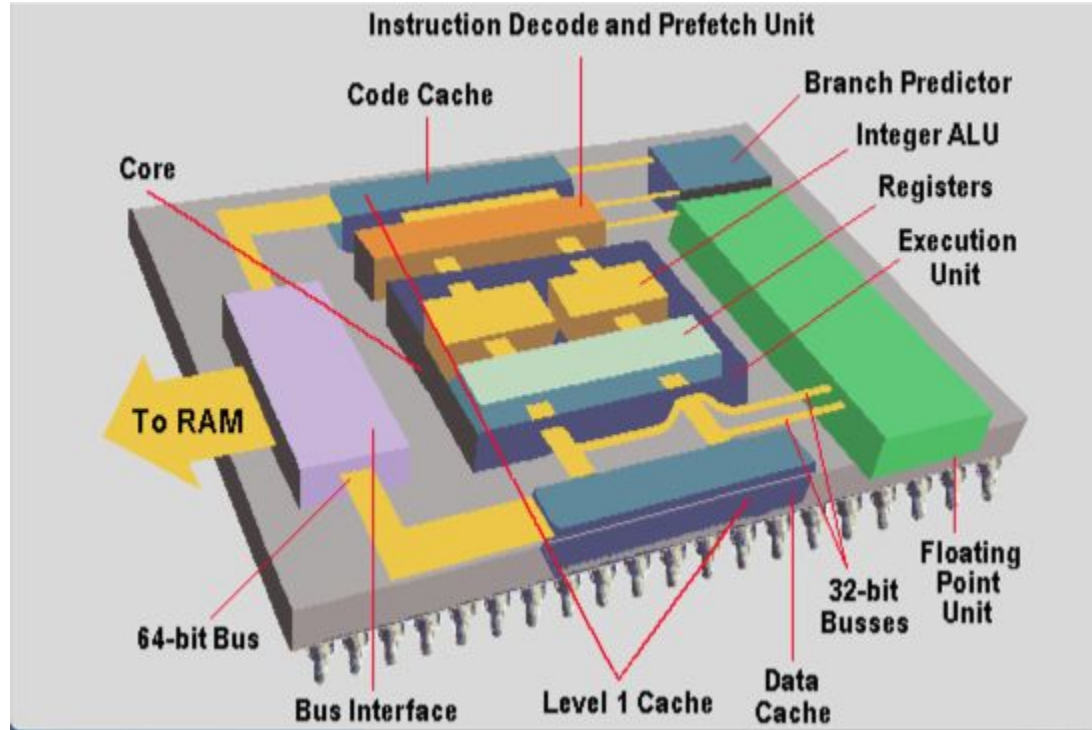

```
1  # Hello World
2
3  .data
4  msg:    .asciiz    "Hello world!"
5
6  .text
7  main:
8          li $v0, 4
9          la $a0, msg
10         syscall    # syscall to display message
11
12         # exit program
13         li $v0, 10
14         syscall
15
```

# registers

- In a higher-level language we use variables to hold data
- In assembly language we use registers to hold data

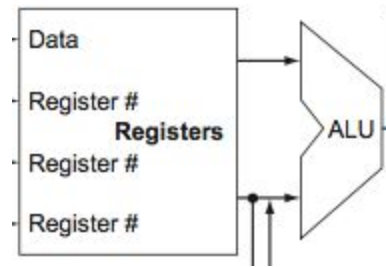

# Registers in the Pentium

# registers

- Used to hold data
- Used to hold addresses

# registers

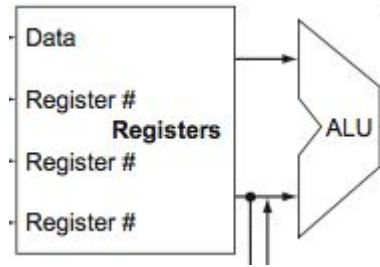

- Registers hold data for operations

Generic processor:

```
add R1, R2, R3
```

MIPS:

```
add $t0, $t1, $t2 # t0 = t1 + t2
```

# MIPS instruction format

- All arithmetic/logic instructions have this format:

`Opcode      operand, operand, operand`

- the first operand is the destination
- the last two are source operands
- opcode specifies what action needs to happen

`add $t0, $t1, $t2`

# MIPS registers

- MIPS has 32 registers
- Each register is 32-bits (1 word, 4 bytes)
- For operands, we most often use:
  - The “temporary” registers \$t0 - \$t9
  - The “saved” registers \$s0 - \$s7
  - The “zero” register \$zero which always contains 0 and is read-only

# .data

We defined and initialized 4 words (integers)

This is somewhat like declaring a variable, but there is no “type”

A memory location can contain integers, floats, characters, it's up to you to remember what it is

```
1  # example 1 load a and b, store into c and d
2
3      .data
4  a:   .word 3
5  b:   .word 4
6  c:   .word 9
7  d:   .word 9
8
9      .text
10 main:
11     lw    $t1, a      # load
12     lw    $t2, b
13     sw    $t1, c      # store
14     sw    $t2, d
15
16 exit:
17     li    $v0, 10     # terminate program
18     syscall
19
```

# MIPS program form

- Labels end with :
- Later we'll use these for jumps
  
- Program ends with a syscall to end the program
- Think of this like return(0) in C
- Syscalls need the call number in \$v0

```
1  # example 1 load a and b, store into c and d
2
3      .data
4  a:   .word 3
5  b:   .word 4
6  c:   .word 9
7  d:   .word 9
8
9      .text
10 main:
11     lw    $t1, a      # load
12     lw    $t2, b
13     sw    $t1, c      # store
14     sw    $t2, d
15
16 exit:
17     li    $v0, 10     # terminate program
18     syscall
19
```

# Load-Store (data transfer) instructions

.text

“lw” loads (copies) a word from memory into a register

“sw” stores (copies) a word from a register into memory

MIPS is a load-store architecture

- Cannot “add c, a, b”
- Cannot “sw c, a”

```
1  # example 1 load a and b, store into c and d
2
3      .data
4  a:   .word 3
5  b:   .word 4
6  c:   .word 9
7  d:   .word 9
8
9      .text
10 main:
11     lw    $t1, a      # load
12     lw    $t2, b
13     sw    $t1, c      # store
14     sw    $t2, d
15
16 exit:
17     li    $v0, 10     # terminate program
18     syscall
19
```

# Load-Store (data transfer) instructions

.text

- Array version of previous program
- “la” loads address

Load/store instruction format:

```
lw $t0, 8($t1)
```

Load memory location  $\$t1+8$  into  $\$t0$

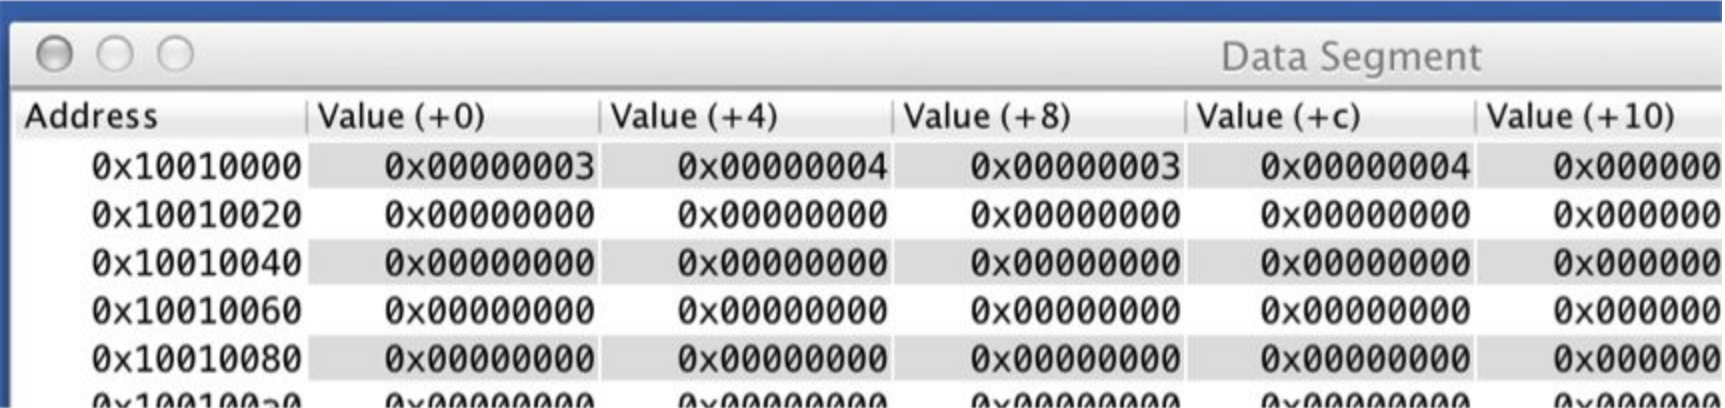

```
1      .data
2 1      .data
3 2  arr1: .word 3, 4
4 3  arr2: .word 9, 9
5 4
6 5      .text
7 6  main:
8 7      la    $t1, arr1
9 8      la    $t2, arr2
10 9     lw    $t0, ($t1)
11 10    sw    $t0, ($t2)
12 11    lw    $t0, 4($t1)
13 12    sw    $t0, 4($t2)
14 13
15 14  exit: li    $v0, 10
16 15    syscall
17 16
17 17
```

# MARS (MIPS Assembler and Runtime Simulator)

- Registers on the right
- Toggle Edit/Execute
- Drop-down buttons on bottom left to expand window
- Edit file, save with .asm
- Assemble icon on top

# After the run

The image shows a screenshot of a debugger's 'Data Segment' window. The window has a title bar with three window control buttons (minimize, maximize, close) on the left and the text 'Data Segment' on the right. Below the title bar is a table with six columns: 'Address', 'Value (+0)', 'Value (+4)', 'Value (+8)', 'Value (+c)', and 'Value (+10)'. The table contains six rows of data. The first row shows values 0x00000003, 0x00000004, 0x00000003, and 0x00000004 at addresses 0x10010000, 0x10010020, 0x10010040, and 0x10010060 respectively. The remaining rows show zero values at addresses 0x10010080, 0x100100a0, and 0x100100c0.

Address	Value (+0)	Value (+4)	Value (+8)	Value (+c)	Value (+10)
0x10010000	0x00000003	0x00000004	0x00000003	0x00000004	0x00000000
0x10010020	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000
0x10010040	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000
0x10010060	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000
0x10010080	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000
0x100100a0	0x00000000	0x00000000	0x00000000	0x00000000	0x00000000

# Practice

Modify program to swap the contents of a and b

```
1 # example 1 load a and b, store into c and d
2
3     .data
4 a:   .word 3
5 b:   .word 4
6 c:   .word 9
7 d:   .word 9
8
9     .text
10 main:
11     lw    $t1, a           # load
12     lw    $t2, b           # load
13     sw    $t1, c           # store
14     sw    $t2, d           # store
15
16 exit:
17     li    $v0, 10          # terminate program
18     syscall
19
```

# ADD and SUB instructions

add rd, rs, rt # rd = rs + rt

sub rd, rs, rt # rd = rs - rt

addi rd, rs, constant # rd = rs + constant

# Simple addi example

```
1 # simple addi example
2 .data
3 var1: .word 4           # variable var1 = 4
4 .text
5 main: li $t1, 2         # $t1 = 2
6      addi $t1, $t1, 3   # now $t1 = 2 + 3
7      addi $t1, $t1, 4   # now $t1 = 2 + 3 + 4
8      sw $t1, var1      # store $t1 in var1
9
10     # exit
11     li $v0, 10
12     syscall
```

# Practice

Write a program to load 3 integers, stored as var1, var2, and var3, into registers \$t1, \$t2, and \$t3. Reserve a word for 'result' and initialize it to 9.

compute  $\$t1 + \$t2 - \$t3$ , this will take 2 instructions

Store the result in 'result'

# More practice

Convert this C expression into MIPS code

```
result = (var2 - var1) + (var3 - var1)
```

# syscalls

The syscall instruction calls the operating system to perform some task that a program would not have permission to do, such as I/O.

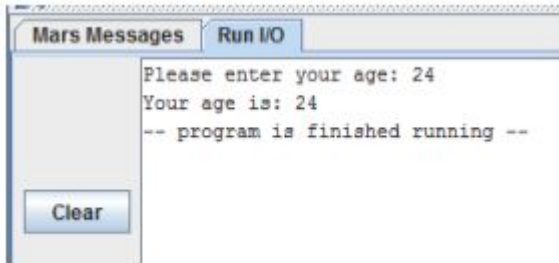

Supported syscalls in MIPS:

- <http://courses.missouristate.edu/KenVollmar/mars/Help/SyscallHelp.html>

# Program termination syscall

```
li $v0, 10 # terminate program  
syscall
```

# I/O syscall demo

```
1  # MARS syscalls
2
3  .data
4  age:    .word    0
5  msg1:   .asciiz  "Please enter your age: "
6  msg2:   .asciiz  "Your age is: "
7
8  .text
9  main:
10
11     # prompt user for age
12     la    $a0, msg1
13     li    $v0, 4
14     syscall
15     # get int from user
16     li    $v0, 5
17     syscall
18     sw    $v0, age
19
20     # echo data to user
21     la    $a0, msg2
22     li    $v0, 4
23     syscall
24     lw    $a0, age
25     li    $v0, 1
26     syscall
27
28  exit:  li    $v0, 10
        syscall
```

# summary

- What are registers?
- Name a MIPS register and describe it.
- What kind of data can it contain? Integer? Characters? Address?
- What are opcodes?
- What are operands?
- What kinds of operands have we seen?

# Coding Practice

For next class, write a program to:

- get the user's name
- get the user's age
- get a neighbor's name
- get the neighbor's age
- print a message echoing both names and the combined years of wisdom
- print a message with the difference in ages
