

#### **Logistic Regression**

#### Nicholas Ruozzi University of Texas at Dallas

based on the slides of Vibhav Gogate

- Supervised learning via naive Bayes
  - Use MLE to estimate a distribution p(x, y) = p(y)p(x|y)
  - Classify by looking at the conditional distribution, p(y|x)
- Today: logistic regression

# Logistic Regression

- Learn p(Y|X) directly from the data
  - Assume a particular functional form, e.g., a linear classifier p(Y = 1|x) = 1 on one side and 0 on the other
  - Not differentiable...
    - Makes it difficult to learn
    - Can't handle noisy labels

p(Y = 1 | x) = 1

# Logistic Regression

- Learn p(y|x) directly from the data
  - Assume a particular functional form

$$p(Y = -1|x) = \frac{1}{1 + \exp(w^T x + b)}$$

$$p(Y = 1|x) = \frac{\exp(w^T x + b)}{1 + \exp(w^T x + b)}$$

#### Logistic Function in m Dimensions

$$p(Y = -1|x) = \frac{1}{1 + \exp(w^T x + b)}$$

## Functional Form: Two classes

- Given some w and b, we can classify a new point x by assigning the label 1 if p(Y = 1|x) > p(Y = -1|x) and -1 otherwise
  - This leads to a linear classification rule:
    - Classify as a 1 if  $w^T x + b > 0$
    - Classify as a -1 if  $w^T x + b < 0$

$$(w^*, b^*) = \arg \max_{w, b} \prod_{i=1}^N p(y^{(i)} | x^{(i)}, w, b)$$

- This is the not the same strategy that we used in the case of naive Bayes
  - For naive Bayes, we maximized the log-likelihood

# Generative vs. Discriminative Classifiers

#### Generative classifier: (e.g., Naïve Bayes)

- Assume some **functional form** for p(x|y), p(y)
- Estimate parameters of p(x|y), p(y) directly from training data
- Use Bayes rule to calculate p(y|x)
- This is a generative model
  - Indirect computation of p(Y|X) through Bayes rule
  - As a result, can also generate a sample of the data,  $p(x) = \sum_{y} p(y)p(x|y)$

**Discriminative classifiers**: (e.g., Logistic Regression)

- Assume some functional form for p(y|x)
- Estimate parameters of p(y|x) directly from training data
- This is a discriminative model
  - Directly learn p(y|x)
  - But cannot obtain a sample of the data as p(x) is not available
  - Useful for discriminating labels

### Learning the Weights

$$\ell(w,b) = \ln \prod_{i=1}^{N} p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \ln p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln p(Y = 1|x^{(i)}, w, b) + \left(1 - \frac{y^{(i)} + 1}{2}\right) \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln \frac{p(Y = 1|x^{(i)}, w, b)}{p(Y = -1|x^{(i)}, w, b)} + \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \left(w^{T}x^{(i)} + b\right) - \ln(1 + \exp(w^{T}x^{(i)} + b))$$

#### Learning the Weights

$$\ell(w,b) = \ln \prod_{i=1}^{N} p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \ln p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln p(Y = 1|x^{(i)}, w, b) + \left(1 - \frac{y^{(i)} + 1}{2}\right) \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln \frac{p(Y = 1|x^{(i)}, w, b)}{p(Y = -1|x^{(i)}, w, b)} + \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} (w^{T}x^{(i)} + b) - \ln(1 + \exp(w^{T}x^{(i)} + b))$$

This is concave in *w* and *b*: take derivatives and solve!

$$\ell(w,b) = \ln \prod_{i=1}^{N} p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \ln p(y^{(i)}|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln p(Y = 1|x^{(i)}, w, b) + \left(1 - \frac{y^{(i)} + 1}{2}\right) \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \ln \frac{p(Y = 1|x^{(i)}, w, b)}{p(Y = -1|x^{(i)}, w, b)} + \ln p(Y = -1|x^{(i)}, w, b)$$
  

$$= \sum_{i=1}^{N} \frac{y^{(i)} + 1}{2} \left(w^{T} x^{(i)} + b\right) - \ln(1 + \exp(w^{T} x^{(i)} + b))$$

No closed form solution  $\boldsymbol{\boldsymbol{\varpi}}$ 

$$\frac{\partial \ell}{\partial b} = \sum_{i=1}^{N} \left[ \frac{y^{(i)} + 1}{2} - p(Y = 1 | x^{(i)}, w, b) \right]$$
$$\frac{\partial \ell}{\partial w_j} = \sum_{i=1}^{N} x_j^{(i)} \left[ \frac{y^{(i)} + 1}{2} - p(Y = 1 | x^{(i)}, w, b) \right]$$

Priors

- Can define priors on the weights to prevent overfitting
  - Normal distribution, zero mean, diagonal covariance

$$p(w) = \prod_{j} \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{w_j^2}{2\sigma^2}\right)$$

- "Pushes" parameters towards zero
- Regularization
  - Helps avoid very large weights and overfitting

### **Priors as Regularization**

• The log-MAP objective with this Gaussian prior is then

$$\ln \prod_{i=1}^{N} p(y^{(i)} | x^{(i)}, w, b) p(w) p(b) = \left[ \sum_{i=1}^{N} \ln p(y^{(i)} | x^{(i)}, w, b) \right] - \frac{\lambda}{2} ||w||_{2}^{2}$$

- Quadratic penalty: drives weights towards zero
- Adds a negative linear term to the gradients
- Different priors can produce different kinds of regularization

### **Priors as Regularization**

• The log-MAP objective with this Gaussian prior is then

$$\ln \prod_{i=1}^{N} p(y^{(i)} | x^{(i)}, w, b) p(w) p(b) = \left[ \sum_{i=1}^{N} \ln p(y^{(i)} | x^{(i)}, w, b) \right] - \frac{\lambda}{2} \|w\|_{2}^{2}$$

• Quadratic penalty: drives weights towards zero

Somtimes called an  $\ell_2$ 

- Adds a negative linear term to the gradients regularizer
- Different priors can produce different kinds of regularization

#### Regularization

#### NB vs. LR (on UCI datasets)

..... Logistic Regression

[Ng & Jordan, 2002]

#### LR in General

- Suppose that y ∈ {1, ..., R}, i.e., that there are R different class labels
- Can define a collection of weights and biases as follows
  - Choose a vector of biases and a matrix of weights such that for y ≠ R

$$p(Y = k|x) = \frac{\exp(b_k + \sum_i w_{ki} x_i)}{1 + \sum_{j < R} \exp(b_j + \sum_i w_{ji} x_i)}$$

and

$$p(Y = R | x) = \frac{1}{1 + \sum_{j < R} \exp(b_j + \sum_i w_{ji} x_i)}$$
