

critical that both Congress and the Administration understand what the constituents' priorities are," he said. "There is a broader user community out there that needs to represent itself. I don't think that is in conflict with supporting this budget. It's recognizing that in a democracy, the people have a say in the priorities of the government."

Constituents already appear to be lining up to help the Survey. Leslie Coleman, director of statistical services at the National Mining Association, noted that a justification for cutting the Mineral Resources Program is that the federal

government should not be in the business of collecting minerals data. However, she said that neither the states nor industry are in the position to gather this information.

Nevada state geologist Jonathan Price, former president of the Association of American State Geologists (AASG), said, "It is disappointing to see yet another cut proposed for the minerals program of that magnitude." He said AASG would likely ask Congress to restore this and other programs.

USGS Coalition cochair Craig Schiffries, director for geoscience policy with the Geolog-

ical Society of America, said the "disappointing" budget cut is part of a pattern over the past 10 years with the Administration proposing cuts that Congress then restores. However, he called this a "risky strategy" because in some cases the funding is not fully restored. He said the Coalition, an alliance of 70 organizations including AGU, supports increased federal investment in USGS programs.

U.S. Passive Margins: Are We Missing an Important Opportunity?

PAGES 64–65

Understanding passive margins—thick accumulations of sediments built above the juncture between continental and oceanic crusts—has far-reaching economic and societal implications. Passive margins underlie the coastal regions of most of the conterminous United States, extending continuously from Texas eastward to Florida and northward to Maine. They hide most of the undiscovered hydrocarbon reserves of the United States, and they are excellent sites for sequestering carbon dioxide. Natural hazards of hurricanes, tsunamis, sea level rise, and rapid subsidence, and concerns related to the United Nations Law of the Sea, also make it imperative to better understand passive margins, and how they form and evolve.

Economic and societal concerns provide natural avenues for explaining the importance of this and other hypothesis-driven geoscientific research efforts to U.S. taxpayers and political leaders, especially because much of the U.S. population lives on or near our passive margins. Linkages between fundamental geoscientific research and societal issues are relatively visible and easy to explain to residents of the tectonically active western United States, and comprehensive studies of U.S. passive margins present a similar opportunity to reach and teach residents of the eastern and southern United States. Furthermore, the economic potential of passive margins invites joint study and sharing of data by industrial and academic scientists.

Existing National Science Foundation Programs and Existing Targets

Despite compelling reasons for studying passive margins, the U.S. scientific community is missing the unique opportunity presented by the U.S. National Science Foundation's (NSF) EarthScope initiative to study these important geologic features. EarthScope is an NSF Earth science program to explore the four-dimen-

sional (4-D) structure of the North American continent. EarthScope provides a framework for integrated studies across the Earth sciences, built around the EarthScope Facility, which consists of the Plate Boundary Observatory (PBO), the San Andreas Fault Observatory at Depth (SAFOD), and the USArray of transportable seismometers (www.earthscope.org). The USArray—the most important potential tool for studying passive margins—is being incrementally deployed from west to east across the United States to image mantle structure, and it is scheduled to reach the Texas coast in 2010 and Maine in 2013.

The GeoSwath initiative is an EarthScope effort linked to the USArray to integrate geology and geophysical imaging to better understand the 4-D evolution of the continental United States. GeoSwath emphasizes a continuous coast-to-coast perspec-

tive across the continent's major geologic provinces (Tikoff et al. [2006]; see also <http://www.globalchange.umich.edu/ben/geoswath/>). We support the GeoSwath initiative and recognize the need to concentrate effort in a few sites (currently seven focus regions plus a xenolith database). However, USArray and GeoSwath, in their present design, stop at the waterline, ignoring the opportunity to study passive margins. Fully 30% of North American continental crust lies beyond the shoreline [Cogley, 1984].

The continental United States is located mostly on the North American tectonic plate. The western boundary of the continental United States and this plate mostly correspond. In contrast, passive margins occur in plate interiors, but they are just as important as plate boundaries for understanding continental evolution. Passive margins are built above broad transitional zones, several hundred kilometers across, between distinct continental and oceanic lithospheres.

Only by studying passive margins can we understand how oceanic and continental crust and mantle merge. This lithospheric transition is buried beneath many kilometers of sediments, and it is impossible to study except with the sorts of geophysical

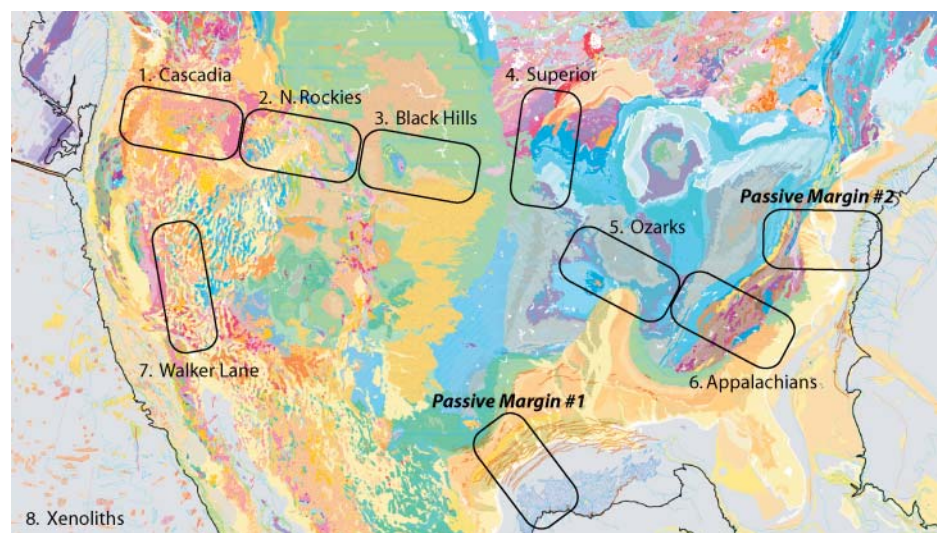

Fig. 1. The GeoSwath focus areas numbered 1–7 plus xenolith database [Tikoff et al., 2006] placed on the 2005 Geologic Map of North America [Reed et al., 2005]. We have deleted the coastline and emboldened the 3000-meter isobath to stress the point that continental geology does not stop at the coastline. Additional boxes labeled Passive Margin #1 and Passive Margin #2 are just two of many possible candidate focus areas where the U.S. passive continental margins could be studied. Figure modifications thanks to E. A. Hinz.

tools that USArray and GeoSwath will use. We should not pretend to understand the nature and evolution of the North American continent if we do not understand the passive margin lithospheric transition.

As presently envisioned, Earthscope will not study U.S. passive margins. The GeoSwath initiative addresses passive margin development only indirectly, by studying—within the proposed on-land Appalachian focus site—an ancient passive margin disrupted by younger deformation, magmatism, and uplift. This entails reconstructing deformed and incomplete crustal sections, and it will provide few new insights about how the transition between continental and oceanic lithosphere occurs.

Understanding U.S. passive margins is too important to remain a secondary objective of Earthscope and GeoSwath; it deserves to be a high priority of both. We suggest that two additional focus regions be designed to similarly study the U.S. continental margins along the Atlantic and Gulf of Mexico coasts (Figure 1).

We may also be able to use existing NSF programs in addition to Earthscope to study passive margins; the NSF-MARGINS initiative recognizes the importance of understanding incipient passive margins through its Rupturing Continental Lithosphere (RCL) experiment (<http://www.nsf-margins.org/RCL/RCL.html>). RCL focuses on active examples of continental breakup, especially in the Gulf of California focus site (a second focus site in the Red Sea was surrendered because of security concerns in the Middle East). Mature passive margins like those of the eastern and southern United States will not be studied by RCL as presently articu-

lated. Another NSF program that could beneficially link to Earthscope and MARGINS is the nascent NSF Ocean Observatories Initiative (<http://www.orionprogram.org/OOI/>).

It will not be easy to study the deeply buried lithospheric structure beneath passive margins. We also appreciate that USArray and GeoSwath are focused on land studies, and that the shoreline has traditionally marked an operational boundary between land and marine geoscientific efforts. Whatever these obstacles, the fact remains that much of the U.S. continent lies beyond the shoreline and that better understanding of the transition between continent and ocean is of paramount importance to the U.S. geoscientific community and broader society.

A Call to Action

We call on the U.S. geoscientific community to discuss how best to reconfigure existing geoscientific initiatives to help Earthscope study passive margins. Perhaps the Earthscope science plan could be modified so that submerged continental lithosphere and the transition to true oceanic lithosphere is included. Or perhaps the MARGINS science plan, specifically RCL, could be modified to include mature passive margins as a research priority.

Another possibility is for Earthscope and MARGINS-RCL to jointly study passive margins. A first step was made at the second national Earthscope meeting in Monterey, Calif. (March 2007), when two joint GeoSwath/MARGINS workshops separately evaluated possibilities for collaboration at the active continental margin in the Pacific Northwest and across the actively forming passive

margin from the Gulf of California to the Salton Trough. MARGINS is contemplating a second decade of its mission and could expand it to study passive margins. GeoSwath and Earthscope should look to a future in which funding has grown to allow for the incorporation of target areas that bestride our passive margins, and for USArray-type deployments that extend offshore to the true continental boundary—not limited by the shoreline that is a cartographic irrelevance to our scientific community's scientific goals.

Only if such creativity fails need we consider developing a new geoscientific initiative specifically to study U.S. passive margins. We invite readers to share their ideas for the future synergistic development and enhancement of the Earthscope, GeoSwath, and MARGINS programs to include study of this critical component of our nation.

MEETINGS

Continental Margins: Linking Ecosystems

Impacts of Global, Local and Human Forcings on Biogeochemical Cycles and Ecosystems, IMBER/LOICZ Continental Margins Open Science Conference; Shanghai, China, 17–21 September 2007

PAGE 64

More than 100 scientists from 25 countries came together to address global, regional, local, and human pressures interactively affecting continental margin biogeochemical cycles, marine food webs, and society. Continental margins cover only 12% of the global ocean area yet account for more than 30% of global oceanic primary production. In addition, continental margins are the most intensely used regions of the world's ocean for natural commodities, including productive fisheries and mineral and petroleum resources. The land adjacent to continental margins hosts about 50% of the world's population, which will bear many direct impacts of global change on coastal

margins. Understanding both natural and human-influenced alterations of biogeochemical cycles and ecosystems on continental margins and the processes (including feedbacks) that threaten sustainability of these systems is therefore of global interest.

The purposes of the meeting were to (1) improve understanding of the linked biogeochemical, physical, and human dimensions of continental margin systems; (2) develop accurate predictive capacity for continental margin responses to environmental and anthropogenic drivers; and (3) outline mechanisms for improved understanding of accelerating global change on continental margins and human society.

The approach—to integrate research and resource management strategies of the Inte-

grated Marine Biogeochemistry and Ecosystem Research (IMBER) and Land-Ocean Interaction in the Coastal Zone (LOICZ) programs—addressed the continuum across nearshore coastal waters (integrated with watersheds), the continental shelf, the shelf break, and the upper slope of the open ocean.

Over the next 3 months, Jack Middelburg and Nancy Rabalais, coconveners of the conference and cohosts of the Continental Margins Task Team, will coordinate a working group to synthesize the findings and recommendations of the meeting. The result will be a research plan that combines the strengths of the IMBER and LOICZ projects and brings the resources of many nations to this area of research.

Important features of the draft plan involve studying:

- carbon and nitrogen transformations and transfers along and across continental margins and at benthic-pelagic and air-sea interfaces,
- present conditions and fit-for-purpose predictive capability for climate change scenarios,
- processes linking biogeochemical processes, primary and secondary production, and living resources,
- continental margins as sources or sinks of CO₂ and potential shifts with increasing
